Hubble's Tuning Fork

Bulges of lenticulars are very similar to ellipticals. Their disk are similar to those of early type spirals, but they have no spiral arms.

B/T ratios, colors and spectral properties, neutral and molecular gas fraction, star formation rate, average luminosity, M/L ratio are intermediate to ellipticals and spirals.

Lenticular galaxies are a morphological transition class between ellipticals and early type spirals.

• *N-body simulations indicate that the bulge component of massive (luminous) lenticulars formed from major mergers.*

• *But bulges in the less luminous elliptical probably formed from minor mergers or accretion events. Stripping of gas from the halo and disk lead to a change in morphology.*

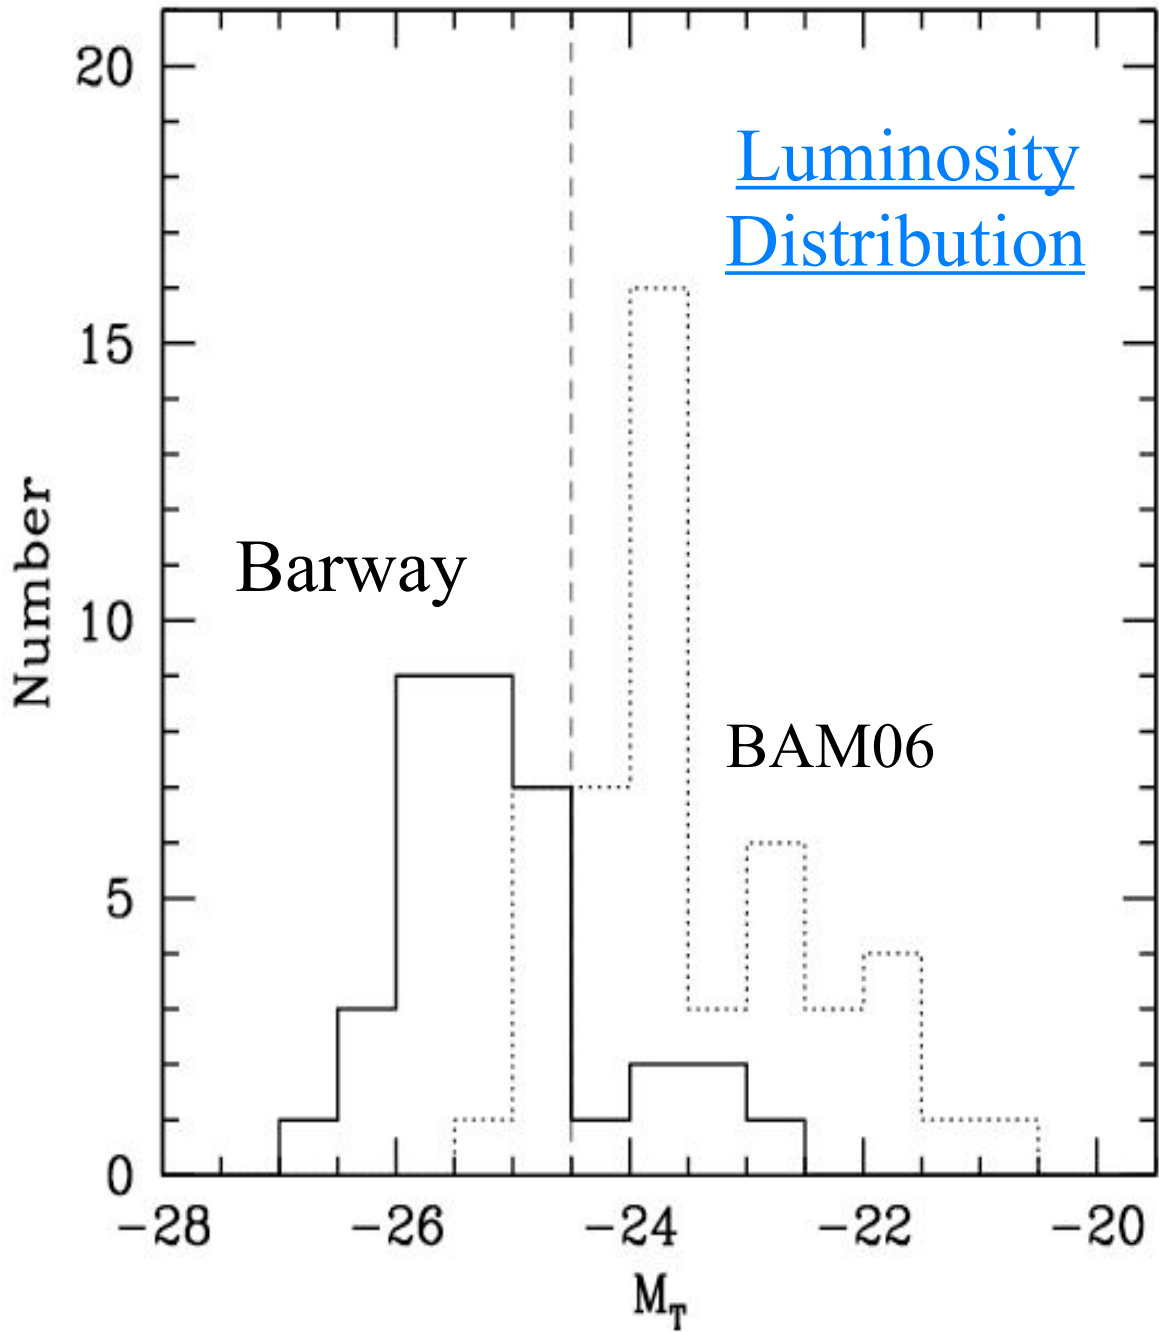

• *Correlation between photometric parameters can be a signature of the formation mechanism.*

Luminosity as
Differentiator

Positive correlation in low-luminosity lenticulars implies that they formed by the stripping of gas from spirals, whose bulges formed through secular evolution.

Bulges of more luminous lenticulars have likely formed through major mergers and rapid collapse.

Selection from
Kormendy
Diagram

Superior to
 $n < 2, n > 2$
criterion

Pseudobulge Selection from Kormendy Diagram

All pseudobulge hosting galaxies are faint.

Classical bulges can occur in faint as well as bright galaxies .

About 20% of faint galaxies contain pseudobulges.
If bright and faint galaxies actually have the same fraction of pseudobulges, the probability of not finding a single pseudobulge in bright galaxies is $\sim 10^{-4}$.

$r_e - r_d$
Correlation

$r_e - r_d$ Correlation

For a given r_e , r_d is on average smaller for the pseudobulges.

$\mu_d(0) - r_d$
Correlation

$\mu_d(0) - r_d$ Correlation

For a given r_d , the disks hosting a pseudobulge are fainter than the ones hosting a classical bulge.

Environmental Dependence

Environmental Dependence

Cluster lenticulars appear to have faded relative to field lenticulars. They could be early type spirals which have lost gas due to ram pressure stripping or galaxy harassment.

Environmental Dependence

Field lenticulars show clear anti-correlation. Cluster lenticulars are restricted to a limited region and show downward scatter. This is consistent with removal of gas from the disk (and bulge) in cluster lenticulars.
